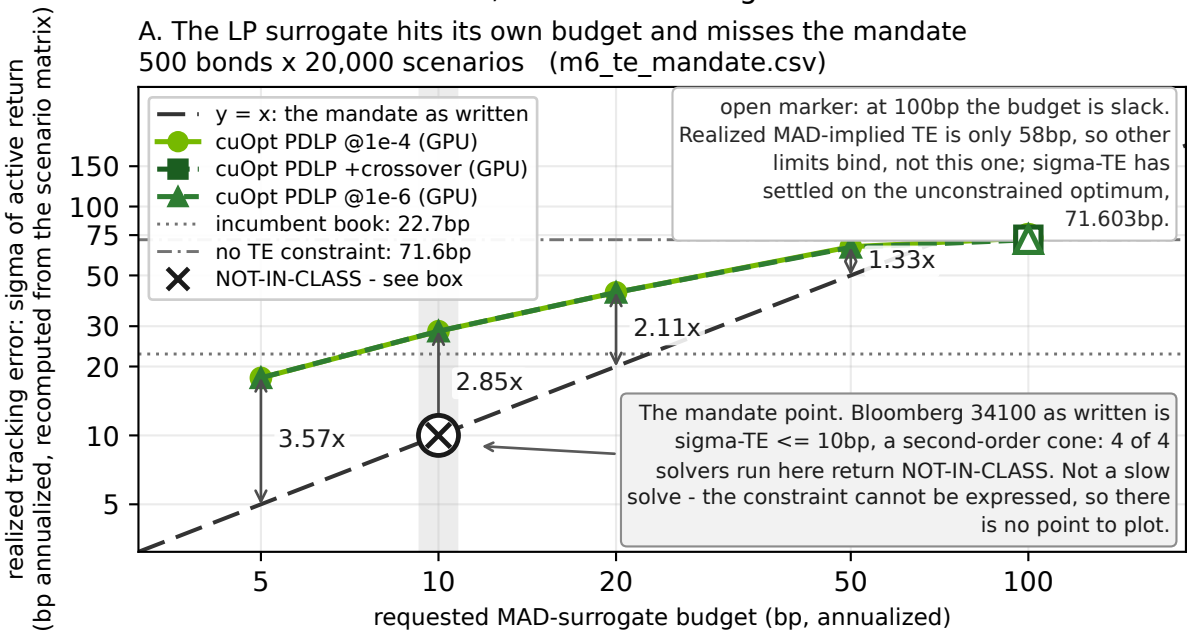
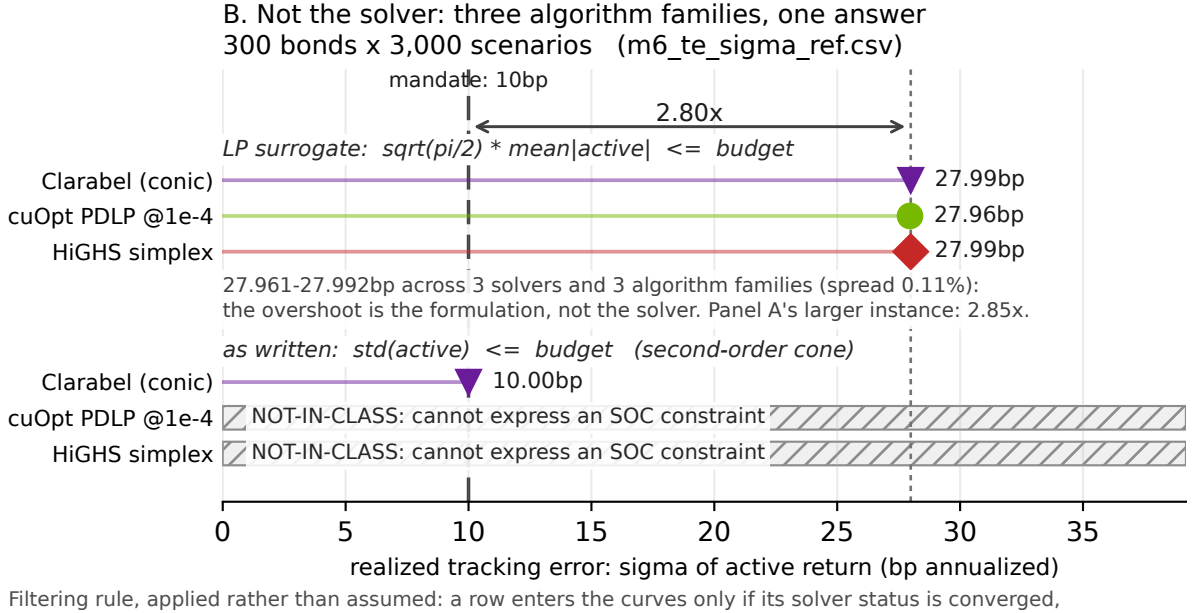
A mandate no LP solver can take, and an LP surrogate that does not deliver it





Filtering rule, applied rather than assumed: a row enters the curves only if its solver status is converged, which drops cuOpt +crossover 4 of 5; HiGHS simplex 5 of 5 (1 returned a solver error, 8 hit the time cap; none carries a recomputed tracking error). Filled marker = the budget binds; open = converged but slack by over 5%. NOT-IN-CLASS in panel A: cuOpt PDLP @1e-4, cuOpt PDLP @1e-6, cuOpt +crossover, HiGHS simplex.

Why the identity line is also the Gaussian line: src/credit.py constrains sqrt(pi/2) * mean|A_c| <= budget and reports that same sigma-scaled quantity, so on Gaussian active returns the surrogate would land exactly on y = x. Every bp above the line is measured non-normality, not a unit conversion.
